On the group of purely inseparable points of an abelian variety defined over a function field of positive characteristic

Damian RÖSSLER*

November 30, 2012

Abstract

Let $K$ be the function field of a smooth and proper curve $S$ over an algebraically closed field $k$ of characteristic $p > 0$. Let $A$ be an ordinary abelian variety over $K$. Suppose that the Néron model $\mathcal{A}$ of $A$ over $S$ has a closed fibre $\mathcal{A}_s$, which is an abelian variety of $p$-rank 0. We show that under these assumptions the group $A(K_{\text{perf}})/\text{Tr}_{K/k}(A)(k)$ is finitely generated. Here $K_{\text{perf}} = K^{p^{-\infty}}$ is the maximal purely inseparable extension of $K$. This result implies that in some circumstances, the ”full” Mordell-Lang conjecture, as well as a conjecture of Esnault and Langer, are verified.

1 Introduction

Let $k$ be an algebraically closed field of characteristic $p > 0$ and let $S$ be a connected, smooth and proper curve over $k$. Let $K := \kappa(S)$ be its function field. If $V/S$ is a locally free coherent sheaf on $S$, we denote by

$$0 = V_0 \subseteq V_1 \subseteq V_2 \subseteq \cdots \subseteq V_{\text{hn}(V)} = V$$

*Institut de Mathématiques, Equipe Emile Picard, Université Paul Sabatier, 118 Route de Narbonne, 31062 Toulouse cedex 9, FRANCE, E-mail: rossler@math.univ-toulouse.fr
the Harder-Narasimhan filtration of $V$. We write as usual

$$\deg(\ast) := \deg(c_1(\ast)), \ \mu(\ast) := \deg(\ast)/\text{rk}(\ast)$$

and

$$\mu_{\text{min}}(V) := \mu(V/V_{\text{hn}(V)})^{-1}, \ \mu_{\text{max}}(V) := \mu(V_1).$$

See [2, chap. 5] (for instance) for the definition of the Harder-Narasimhan filtration and for the notion of semistable sheaf, which underlies it.

A locally free sheaf $V$ on $S$ is said to be strongly semistable if $F^r\ast S(V)$ is semistable for all $r \in \mathbb{N}$. Here $F_S$ is the absolute Frobenius endomorphism of $S$. A. Langer proved in [16, Th. 2.7, p. 259] that there is an $n_0 = n_0(V) \in \mathbb{N}$ such that the quotients of the Harder-Narasimhan filtration of $F_S^{n_0}\ast(V)$ are all strongly semistable. This shows in particular that the following definitions :

$$\bar{\mu}_{\text{min}}(V) := \lim_{l \to \infty} \mu_{\text{min}}(F_l^{n_0}(V))/p^l$$

and

$$\bar{\mu}_{\text{max}}(V) := \lim_{l \to \infty} \mu_{\text{max}}(F_l^{n_0}(V))/p^l$$

make sense.

With these definitions in hand, we are now in a position to formulate the results that we are going to prove in the present text.

Let $\pi : \mathcal{A} \to S$ be a smooth commutative group scheme and let $A := A_K$ be the generic fibre of $\mathcal{A}$. Let $\epsilon : S \to \mathcal{A}$ be the zero-section and let $\omega := \epsilon^*(\Omega^1_{A/S})$ be the Hodge bundle of $\mathcal{A}$ over $S$.

Fix an algebraic closure $\bar{K}$ of $K$. For any $\ell \in \mathbb{N}$, let

$$K^{p^{-\ell}} := \{x \in \bar{K} | x^{p^{\ell}} \in K\},$$

which is a field. We may then define the field

$$K^{\text{perf}} = K^{p^{-\infty}} = \cup_{\ell \in \mathbb{N}} K^{p^{-\ell}},$$

which is often called the perfection of $K$.

**Theorem 1.1.** Suppose that $A/S$ is semiabelian and that $A$ is a principally polarized abelian variety. Suppose that the vector bundle $\omega$ is ample. Then there exists $\ell_0 \in \mathbb{N}$ such the natural injection $A(K^{p^{-\ell_0}}) \hookrightarrow A(K^{\text{perf}})$ is surjective (and hence a bijection).
For the notion of ampleness, see [12, par. 2]. A smooth commutative $S$-group scheme $A$ as above is called semiabelian if each fibre of $A$ is an extension of an abelian variety by a torus (see [6, 1, def. 2.3] for more details).

We recall the following fact, which is proven in [1]: a vector bundle $V$ on $S$ is ample if and only if $\overline{\mu}_{\min}(V) > 0$.

**Theorem 1.2.** Suppose that $A$ is an ordinary abelian variety. Then

(a) $\overline{\mu}_{\min}(\omega) \geq 0$;

(b) if there is a closed point $s \in S$ such that $A_s$ is an abelian variety of $p$-rank $0$, then $\overline{\mu}_{\min}(\omega) > 0$.

**Corollary 1.3.** Suppose that $A$ is ordinary and that there is a closed point $s \in S$ such that $A_s$ is an abelian variety of $p$-rank $0$. Then

(a) there exists $\ell_0 \in \mathbb{N}$ such the natural injection $A(K^{p-\ell_0}) \hookrightarrow A(K^{perf})$ is surjective;

(b) the group $A(K^{perf})/\text{Tr}_{K|k}(A)(k)$ is finitely generated.

The notation $\text{Tr}_{K|k}(A)$ refers to the $K|k$-trace of $A$ over $k$. This is an abelian variety over $k$, which comes with a morphism $\text{Tr}_{K|k}(A)_K \to A$. See [4] for the definition.

Here is an application of Corollary 1.3. Suppose until the end of the sentence that $A$ is an elliptic curve over $K$ and that $j(A) \not\in k$ (here $j(\cdot)$ is the modular $j$-invariant); then $\text{Tr}_{K|k}(A) = 0$, $A$ is ordinary and there is a closed point $s \in S$ such that $A_s$ is an elliptic curve of $p$-rank $0$ (i.e. a supersingular elliptic curve); thus $A(K^{perf})$ is finitely generated. This was also proven by D. Ghioca (see [7]) using a different method.

We list two further applications of Theorems 1.1 and 1.2.

Let $Y$ be an integral closed subscheme of $B := A_{\bar{K}}$.

Let $C := \text{Stab}(Y)^{\text{red}}$, where $\text{Stab}(Y) = \text{Stab}_B(Y)$ is the translation stabilizer of $Y$. This is the closed subgroup scheme of $B$, which is characterized uniquely by the fact that for any scheme $T$ and any morphism $b : T \to B$, translation by $b$ on
the product $B \times_K T$ maps the subscheme $Y \times T$ to itself if and only if $b$ factors through $\text{Stab}_B(Y)$. Its existence is proven in [10] exp. VIII, Ex. 6.5 (e)].

The following proposition is a special case of the (unproven) "full" Mordell-Lang conjecture, first formulated by Abramovich and Voloch. See [8] and [19] Conj. 4.2] for a formulation of the conjecture and further references.

**Proposition 1.4.** Suppose that $A$ is an ordinary abelian variety. Suppose that there is a closed point $s \in S$ such that $A_s$ is an abelian variety of $p$-rank 0. Suppose that $\text{Tr}_{K/k}(A) = 0$. If $Y \cap A(K_{\text{perf}})$ is Zariski dense in $Y$ then $Y$ is the translate of an abelian subvariety of $B$ by an point in $B(K)$.

**Proof** (of Proposition 1.4). This is a direct consequence of Corollary 1.3 and of the Mordell-Lang conjecture over function fields of positive characteristic; see [13] for the latter.

Our second application is to a conjecture of A. Langer and H. Esnault. See [5, Remark 6.3] for the latter. The following proposition is a special case of their conjecture.

**Proposition 1.5.** Suppose that $k = \bar{\mathbb{F}}_p$. Suppose that $A$ is an ordinary abelian variety and that there is a closed point $s \in S$ such that $A_s$ is an abelian variety of $p$-rank 0. Suppose that for all $\ell \geq 0$ we are given a point $P_{\ell} \in A^{(p^{\ell})}(K)$ and suppose that for all $\ell \geq 1$, we have $\text{Ver}_{A/K}^{(p^{\ell})}(P_{\ell}) = P_{\ell+1}$. Then $P_0$ is a torsion point.

Here $\text{Ver}_{A/K}^{(p^{\ell})} : A^{(p^{\ell})} \to A^{(p^{\ell-1})}$ is the Verschiebung morphism. See [9] VII_A, 4.3] for the definition.

**Proof** (of Proposition 1.5). By assumption the point $P_0$ is $p^\infty$-divisible in $A(K_{\text{perf}})$, because $[p]_{A/K} = \text{Ver}_{A/K} \circ \text{Frob}_{A/K}$ and $\text{Ver}_{A/K}$ is étale, because $A$ is ordinary. Here $\text{Frob}_{A/K}$ is the relative Frobenius morphism and $[p]_{A/K}$ is the multiplication by $p$ morphism on $A$. Thus the image of $P_0$ in $A(K_{\text{perf}})/\text{Tr}_{K/k}(A)(k)$ is a torsion point because the group $A(K_{\text{perf}})/\text{Tr}_{K/k}(A)(k)$ is finitely generated by Corollary 1.3. Hence $P_0$ is a torsion point because $\text{Tr}_{K/k}(A)(k)$ consists of torsion points. □

**Acknowledgments.** I would like to thank H. Esnault and A. Langer for many interesting conversations on the subject matter of this article.
2 Proof of 1.1, 1.2 & 1.3

2.1 Proof of Theorem 1.1

The idea behind the proof of Theorem 1.1 comes from an article of M. Kim (see [15]).

In this subsection, the assumptions of Theorem 1.1 hold. So we suppose that $A/S$ is semiabelian, that $A$ is a principally polarized abelian variety and that $\omega$ is ample.

If $Z \to W$ is a $W$-scheme and $W$ is a scheme of characteristic $p$, then for any $n \geq 0$ we shall write $Z^{[n]} \to W$ for the $W$-scheme given by the composition of arrows

$$Z \to W^F W.$$  

Now fix $n \geq 1$ and suppose that $A(K^{p^{-n}}) \setminus A(K^{p^{-n+1}}) \neq \emptyset$.

Fix $P \in A^{(p^n)}(K) \setminus A^{(p^{n-1})}(K) = A(K^{p^{-n}}) \setminus A(K^{p^{-n+1}})$. The point $P$ corresponds to a commutative diagram of $k$-schemes

\[
\begin{array}{ccc}
  & A & \\
  P & \downarrow & \\
  \text{Spec } K^{[n]} & \xrightarrow{F^n_K} & \text{Spec } K
\end{array}
\]

such that the residue field extension $K|k(P(\text{Spec } K^{[n]}))$ is of degree 1 (in other words $P$ is birational onto its image). In particular, the map of $K$-vector spaces $P^*\Omega^1_{A/k} \to \Omega^1_{K^{[n]}/k}$ arising from the diagram is non zero.

Now recall that there is a canonical exact sequence

$$0 \to \pi^*_K \Omega^1_{K/k} \to \Omega^1_{A/k} \to \Omega^1_{A/K} \to 0.$$  

Furthermore the map $F^n_K \pi^*_K \Omega^1_{K/k} \to \Omega^1_{K^{[n]}/k}$ vanishes. Also, we have a canonical identification $\Omega^1_{A/K} = \pi^*_K \omega_K$ (see [3] chap. 4., Prop. 2]). Thus the natural surjection $P^*\Omega^1_{A/k} \to \Omega^1_{K^{[n]}/k}$ gives rise to a non-zero map

$$\phi_n : F^n_K \omega_K \to \Omega^1_{K^{[n]}/k}.$$  

The next lemma examines the poles of the morphism $\phi_n$.  

5
We let $E$ be the closed subset, which is the union of the points $s \in S$, such that the fibre $A_s$ is not complete.

**Lemma 2.1.** The morphism $\phi_n$ extends to a morphism of vector bundles

$$F_S^{n,*}\omega \to \Omega^1_{S[n]/k}(E).$$

**Proof** (of 2.1). First notice that there is a natural identification $\Omega^1_{S[n]/k}(log E) = \Omega^1_{S[n]/k}(E)$, because there is a sequence of coherent sheaves

$$0 \to \Omega_{S[n]/k} \to \Omega^1_{S[n]/k}(log E) \to \mathcal{O}_E \to 0$$

where the morphism onto $\mathcal{O}_E$ is the residue morphism. Here the sheaf $\Omega^1_{S[n]/k}(log E)$ is the sheaf of differentials on $S[n] - E$ with logarithmic singularities along $E$. See [14, Intro.] for this result and more details on these notions.

Now notice that in our proof of Theorem [14] we may replace $K$ by a finite extension field $K'$ without restriction of generality. We may thus suppose that $A$ is endowed with an $m$-level structure for some $m \geq 3$.

We now quote part of one the main results of the book [6]:

1. there exists a regular moduli space $A_{g,m}$ for principally polarized abelian varieties over $k$ endowed with an $m$-level structure;
2. there exists an open immersion $A_{g,m} \hookrightarrow A^*_{g,m}$, such that the (reduced) complement $D := A^*_{g,m} \setminus A_{g,m}$ is a divisor with normal crossings and $A^*_{g,m}$ is regular and proper over $k$;
3. the scheme $A^*_{g,m}$ carries a semiabelian scheme $G$ extending the universal abelian scheme $f : Y \to A_{g,m}$;
4. there exists a regular and proper $A^*_{g,m}$-scheme $\tilde{f} : \tilde{Y} \to A^*_{g,m}$, which extends $Y$ and such that $F := \tilde{Y} \setminus Y$ is a divisor with normal crossings (over $k$); furthermore
5. on $\tilde{Y}$ there is an exact sequence of locally free sheaves

$$0 \to \tilde{f}^*\Omega^1_{A_{g,m}/k}(log D) \to \Omega^1_{\tilde{Y}/k}(log F) \to \Omega^1_{\tilde{Y}/A_{g,m}}(log F/D) \to 0,$$
which extends the usual sequence of locally free sheaves

\[ 0 \rightarrow f^*\Omega^1_{A^g,m/k} \rightarrow \Omega^1_Y/k \rightarrow \Omega^1_{Y/A^g,m} \rightarrow 0 \]

on \( A^g,m \). Furthermore there is an isomorphism \( \Omega^1_{Y/A^g,m}(\log F/D) \simeq \bar{f}^*\omega_G \).

Here \( \omega_G := \text{Lie}(G)^\vee \) is the tangent bundle (relative to \( A^g,m \)) of \( G \) restricted to \( A^g,m \) via the unit section.

See \([6, \text{chap. VI, th. 1.1}]\) for the proof.

The datum of \( A/K \) and its level structure induces a morphism \( \phi : K \rightarrow A^g,m \), such that \( \phi^*Y \simeq A \), where the isomorphism respects the level structures. Call \( \lambda : A \rightarrow Y \) the corresponding morphism over \( k \). Let \( \bar{\phi} : S \rightarrow A^g,m \) be the morphism obtained from \( \phi \) via the valuative criterion of properness. By the unicity of semiabelian models (see \([6, \text{chap. I, th. 1.9}]\)), we have a natural isomorphism \( \bar{\phi}^*G \simeq A \) and thus we have a set-theoretic equality \( \bar{\phi}^{-1}(D) = E \) and an isomorphism \( \bar{\phi}^*\omega_G = \omega \). Let also \( \bar{P} \) be the morphism \( S^{[n]} \rightarrow \bar{Y} \) obtained from \( \lambda \circ P \) via the valuative criterion of properness. By construction we now get an arrow

\[ \bar{P}^*\Omega^1_{Y/k}(\log F) \rightarrow \Omega^1_{S^{[n]}/k}(\log E) \]

and since the induced arrow

\[ \bar{P}^*\bar{f}^*\Omega^1_{A^g,m/k}(\log D) = F_{S^*}^{[n]*} \circ \bar{\phi}^*(\Omega^1_{A^g,m/k}(\log D)) \rightarrow \Omega^1_{S^{[n]}/k}(\log E) \]

vanishes (because it vanishes generically), we get an arrow

\[ \bar{P}^*\Omega^1_{Y/A^g,m}(\log F/D) = F_{S^*}^{[n]*} \circ \bar{\phi}^*\omega_G = F_{S^*}^{[n]*}\omega \rightarrow \Omega^1_{S^{[n]}/k}(\log E) = \Omega^1_{S^{[n]}/k}(E), \]

which is what we sought. \( \square \)

To conclude the proof of Proposition \([1.1]\), choose \( l_0 \) large enough so that

\[ \mu_{\text{min}}(F_{S^*}^{[l]*}(\omega)) > \mu(\Omega^1_{S/k}(E)) \]

for all \( l > l_0 \). Such an \( l_0 \) exists because \( \bar{\mu}_{\text{min}}(\omega) > 0 \). Now notice that since \( k \) is a perfect field, we have \( \Omega^1_{S/k}(E) \simeq \Omega^1_{S^{[n]}/k}(E) \). We see that we thus have

\[ \text{Hom}(F_{S^*}^{[l]*}(\omega), \Omega^1_{S^{[n]}/k}(E)) = 0 \]

for all \( l > l_0 \) and thus by Lemma \([2.1]\) we must have \( n < l_0 + 1 \). Thus we have

\[ A(K^{(p^{-1})}) = A(K^{(p^{-l_0+1})}) \]

7
for all \( l \geq l_0 \).

**Remark.** The fact that \( \text{Hom}(F_{S}^{l,*}(\omega), \Omega_{S/k}^{1}(E)) \simeq \text{Hom}(F_{S}^{l,*}(\omega), \Omega_{S/k}^{1}(E)) \) vanishes for large \( l \) can also be proven without appealing to the Harder-Narasimhan filtration. Indeed the vector bundle \( \omega \) is also cohomologically \( p \)-ample (see [17, Rem. 6), p. 91]) and thus there is an \( l_0 \in \mathbb{N} \) such that for all \( l > l_0 \)

\[
\text{Hom}(F_{S}^{l,*}(\omega), \Omega_{S/k}^{1}(E)) = H^0(S, F_{S}^{l,*}(\omega) \otimes \Omega_{S/k}^{1}(E))
\]

Serre duality =

\[
H^1(S, F_{S}^{l,*}(\omega) \otimes \Omega_{S/k}^{1}(E)) = 0.
\]

### 2.2 Proof of Theorem 1.2

In this subsection, we suppose that the assumptions of Theorem 1.2 hold. So we suppose that \( A \) is an ordinary abelian variety.

Notice first that for any \( n \geq 0 \), the Hodge bundle of \( A^{(p^n)} \) is \( F_{S}^{n,*} \omega \). Hence, in proving Proposition 1.2 we may assume without restriction of generality that \( \omega \) has a strongly semistable Harder-Narasimhan filtration.

Let \( V := \omega / \omega_{\text{hn}(\omega)} - 1 \). Notice that for any \( n \geq 0 \), we have a (composition of) Verschiebung(s) map(s) \( \omega \to F_{S}^{n,*} \omega \). Composing this with the natural quotient map, we get a map

\[
\phi : \omega \xrightarrow{\text{Ver}(p^n) \ast} F_{S}^{n,*} V
\]

The map \( \phi \) is generically surjective, because by the assumption of ordinarity the map \( \omega \xrightarrow{\text{Ver}(p^n) \ast} F_{S}^{n,*} \omega \) is generically an isomorphism.

We now prove (a). The proof is by contradiction. Suppose that \( \bar{\mu}_{\text{min}}(\omega) := \mu(V) < 0 \). This implies that when \( n \to \infty \), we have \( \mu(F_{S}^{n,*} V) \to -\infty \). Hence if \( n \) is sufficiently large, we have \( \text{Hom}(\omega, F_{S}^{n,*} V) = 0 \), which contradicts the surjectivity of the map in (1).

We turn to the proof of (b). Again the proof is by contradiction. So suppose that \( \bar{\mu}_{\text{min}}(\omega) \leq 0 \). By (a), we know that we then actually have \( \bar{\mu}_{\text{min}}(\omega) = 0 = \mu(V) \) and \( V \neq 0 \). If \( \bar{\mu}_{\text{max}}(\omega) > 0 \) then the map \( \omega_1 \to F_{S}^{n,*} V \) obtained by composing \( \phi \) with the inclusion \( \omega_1 \hookrightarrow \omega \) must vanish, because

\[
\mu(\omega_1) > \mu(F_{S}^{n,*} V) = p^n \cdot \mu(V) = 0.
\]
Hence we obtain a map $\omega/\omega_1 \to F^n_{S^*}V$. Repeating this reasoning for $\omega/\omega_1$ and applying induction we finally get a map

$$\lambda : V \to F^n_{S^*}V.$$ 

The map $\lambda$ is generically surjective and thus globally injective, since its target and source are locally free sheaves of the same generic rank. Let $T$ be the cokernel of $\lambda$ (which is a torsion sheaf). We then have

$$\deg(V) + \deg(T) = 0 + \deg(T) = \deg(F^n_{S^*}V) = 0$$

and thus $T = 0$. This shows that $\lambda$ is a (global) isomorphism. In particular, the map $\phi$ is surjective. Thus the map

$$\phi_s : \omega_s \to F^n_{S^*}V_s$$

is surjective and thus non-vanishing. This contradicts the hypothesis on the $p$-rank at $s$.

### 2.3 Proof of Corollary 1.3

In this subsection, we suppose that the assumptions of Corollary 1.3 are satisfied. So we suppose that $A$ is ordinary and that there is a closed point $s \in S$ such that $A_s$ is an abelian variety of $p$-rank 0.

We first prove (a). First we may suppose without restriction of generality that $A$ is principally polarized. This follows from the fact that the abelian variety $(A \times_K A^\vee)^4$ carries a principal polarization ("Zarhin’s trick" - see [18, Rem. 16.12, p. 136]) and from the fact that the abelian variety $(A \times_K A^\vee)^4$ also satisfies the assumptions of Corollary 1.3. Furthermore, we may without restriction of generality replace $S$ by a finite extension $S'$. Thus, by Grothendieck’s semiabelian reduction theorem (see [11, IX]) we may assume that $A$ is semiabelian. Statement (a) then follows from Theorems 1.1 and 1.2.

We now turn to statement (b). Let $\tau_{K/k} : \text{Tr}_{K/k}(A)_K \to A$ be the $K/k$-trace morphism. Notice that for any $\ell \geq 0$, we have a natural identification of $k$-group schemes $\text{Tr}_{K/k}(A)^{(p^\ell)} \simeq \text{Tr}_{K/k}(A^{(p^\ell)})$, because the extension $K/K^p$ is primary and $k$ is perfect (see [11, Th. 6.4 (3)]). Thus, if $\ell_0 \in \mathbb{N}$ is the number appearing in (a),
we have identifications
\[
A(K^\text{perf})/\text{Tr}_{K/k}(A)(k) = A(K^{-\ell_0})/\text{Tr}_{K/k}(A)(k) = A(K^{-\ell_0})/\text{Tr}_{K/k}(A)(k^{-\ell_0}) \\
= A(p^{\ell_0}(K))/\text{Tr}_{K/k}(A(p^{\ell_0}))(k) = A(p^{\ell_0})(K)/\text{Tr}_{K/k}(A(p^{\ell_0}))(k)
\]
and the group appearing after the last equality is finitely generated by the Lang-Néron theorem.
